In a 1994 Harris poll of Americans with disabilities, 63 percent of respondents said that the quality of life had improved for people with disabilities during the previous 4 years. Certainly, the 1990 passage of the Americans with Disabilities Act (ADA) has resulted in a much greater awareness of disability and of the barriers that prevent many people with disabilities from participating fully in American society. But statistical evidence for real improvements in the lives of those with disabilities—more opportunities for employment and improved economic status, greater freedom of movement and ease of access, and increased levels of social integration—has been slow to materialize.

Disability Watch, a compendium of data on the status of Americans with disabilities from Disability Rights Advocates and the Disability Statistics Center, offers some good news, as well as ample evidence that further efforts are needed. Recent hints of a possible upturn in employment levels for people with severe disabilities are countered by other data showing a widening gap in income levels for those with disability compared to those without. While there are indications that many barriers in the built environment have been removed, improving accessibility of public buildings and some transportation systems, many problem areas remain. And low levels of participation in social, cultural, and commercial activities do not seem to have increased measurably since the ADA became law.

Employment

Four-fifths (81 percent) of employers responding to a 1995 Harris poll said that they had made accommodations for workers with disabilities, up from half (51 percent) in 1986. But if employers are making greater efforts to provide job opportunities for people with disabilities, national surveys still do not conclusively show increased levels of employment.

Figure 1 shows the trend in employment and labor force participation rates for working-age adults with disabilities from three national surveys. Two surveys reveal no significant trends: The labor force participation rate for people aged 18–64 limited in activity due to chronic health conditions or impairments, obtained from an analysis of the National Health Interview Survey (NHIS), remained more or less constant at about 52 percent between 1990 and 1994; this figure includes those who are either working or actively looking for work. The employment rate of people aged 16–64 with work disabilities (a limitation in the ability to work associated with a chronic health condition or impairment) was also steady, at 28 or 29 percent; these data come from the Census Bureau’s Current Population Survey (CPS) for 1990 through 1995.

The one survey that does show a statistically significant increase is the Survey of Income and Program Participation (SIPP), but for only one of two measures: People aged 21–64 with severe functional limitations (such as an inability to climb a flight of stairs without resting,
Disability Statistics Abstract #21 / May 1998

median monthly income for men with work disabilities averaged $1,880 in 1995—20 percent less than the $2,356 earned by their counterparts without disabilities; women with disabilities earned $1,511 monthly, or 13 percent less than the $1,737 figure for non-disabled women.

As Figure 2 shows, this gap in earnings has not narrowed in recent years. For men, in fact, it has widened considerably. According to data from the SIPP, men with work disabilities who had steady, full-time jobs earned 85 percent of the amount their non-disabled counterparts earned in 1984, compared to only 80 percent in 1995. Women with work disabilities earned 85 percent in 1984, compared to 87 percent in 1995.

All in all, data from the CPS show no improvement in the economic well-being of Americans with disabilities. In 1989, 28.9 percent of working-age adults limited in their ability to work lived in poverty; in 1994, the poverty rate was more or less the same, at 30.0 percent.

Barriers

Physical and communication barriers can limit access by people with disabilities to public buildings, sidewalks, and transportation systems, but it is easy to find evidence that many of these barriers are being removed: Some 12,728 small businesses claimed a tax credit for “disabled access” in 1993; the credit applies to removal of architectural barriers, hiring signers for hearing-impaired customers, and printing documents in Braille or large type or making them available on cassette. Public transportation systems have become more accessible to riders with mobility or sensory impairments; the U.S. Department of Transportation’s estimate that 55 to 60 percent of public transit buses are wheelchair accessible is a twofold increase over the 24 percent that were accessible in 1985. And, on a subjective level, 75 percent of people with disabilities interviewed in a 1994 Harris poll said that access to restaurants, theaters, stores, and museums had improved since the passage of the ADA.

Despite these clear signs of progress, a great many barriers continue to impede the full social participation of people with disabilities. One-quarter (24 percent) of the respondents to the ’94 Harris poll said that access to public buildings

was a problem for them. Some modes of transportation, such as intercity buses and the New York subway system, remain almost totally inaccessible to those limited in mobility; air travel can be partially accessible or completely inaccessible, depending on the type of plane and the presence or absence of a jetway. And only a tiny fraction (2.9 percent, according to 1990 data from the NHIS) of Americans live in homes with any accessibility features,\(^7\) such as ramps, extra-wide doors, elevators, or stair lifts.

**Social Participation**

People with disabilities continue to live in relative social isolation. Among persons living in the community rather than in institutions, those with disabilities are twice as likely to live alone as those without disabilities (19.6 vs. 8.4 percent), according to data from the 1990 NHIS.\(^8\) Half (51 percent) of the respondents to the '94 Harris poll of Americans with disabilities said that lack of a full social life was a problem for them.

Figure 3 shows the levels of participation in specific social, cultural, and commercial activities, according to the 1994 Harris poll. More than twice as many people with disabilities as those without (30 vs. 14 percent) socialize with close friends, relatives, or neighbors less often than once a week. Similarly, twice as many people with disabilities (58 vs. 29 percent) said they had not gone to see a movie in the previous year. Three-fourths hadn’t attended a live music performance (76 percent, compared to 51 percent for those without disabilities), and two-thirds had not attended a sporting event (71 percent, vs. 43 percent for those without disabilities).

Two-thirds (65 percent) of people with disabilities go out to eat less often than once a week, compared to less than half (45 percent) of non-disabled people. Church attendance is lower for people with disabilities (49 percent attend at least once a month, compared to 59 percent for those without disabilities). And, while almost all American adults without disabilities go food shopping at least once a week (85 percent), only just over half (56 percent) of those with disabilities do so.

Comparison with a similar 1986 poll shows no statistically significant change in levels of participation in the above activities. It is therefore clear that, by 1994, the ADA had yet to fulfill one of its principal goals, that of increasing the level of participation by people with disabilities in mainstream American society.
